Implementation for week one

Our first step in implementation will be to create a class for our user profile that will be hold personal data. (E.g, imported data, DOB, Weight ETC) Then our next task is to implement a class or set of classes that will read a set of data. This data will be stored as an object for running that will hold the different stats (E.G speed, time, distance)

After we finish these implementations we will be starting out design on the statistics classes to calculate the averages of the data. This class will take the total amount og data for each run made and calculate the overall mean of the activity,
